ABSTRACT

Super-atmospheric O₂ has been shown to affect respiration rate (RR), but no model describing its effect on RR for pomegranate arils has been reported. This study investigated the effects of four different gas compositions (5 kPa O₂, 10 kPa CO₂ and 85 kPa N₂; 10 kPa O₂, 5 kPa CO₂ and 85 kPa N₂; 70 kPa O₂, 10 kPa CO₂ and 20 kPa N₂; and air) on RR of pomegranate arils (cv. Wonderful) stored at 5°C. Michaelis–Menten enzyme kinetics models were used to investigate the effect of CO₂ inhibition on O₂ consumption rate. Respiratory quotient was used to determine fermentation threshold. The O₂ consumption rate increased from 0.87 to 2.81 mL/kg h, with increase in O₂ concentration from 5 kPa to 70 kPa. All enzyme kinetics model parameters adequately described the influence of gas concentration on aril RR with correlation coefficient (R²_adj = 81–91%).

INTRODUCTION

After harvest, fresh produce are susceptible to increased physiological stress and deterioration in quality due to accelerated respiration rate (RR) (Aindongo, Caleb, Mahajan, Manley, & Opara, 2014; Caleb, Mahajan, Opara, & Witthuhn, 2012a). This process consumes O₂ and produces CO₂ in a series of enzymatic reaction (Iqbal, Rodrigues, Mahajan, & Kerry, 2009). Thus, higher RR could indicate a faster rate of physiological aging, senescence and deterioration of fresh produce (Cliffe-Byenes & O’Beirne, 2007). Improved postharvest handling methods which apply modified atmosphere (MA) around the produce can be used to reduce RR and slow down metabolic processes, thereby maintaining quality and extending shelf life (Belay, Caleb, & Opara, 2016; Caleb et al., 2012a; Jing-Jun et al., 2012).

Studies have reported different approaches to determine suitable gas concentration for reducing the RR of pomegranate arils. Ersan, Gunes, and Zor (2010) investigated the effect of O₂ (2, 10 and 21 kPa) and CO₂ (0, 10 and 20 kPa) concentration on the RR of pomegranate arils (cv. Hicaznaran) at 5°C. Similarly, Banda, Jacobs, and Opara (2015) studied the effect of O₂ (5, 21 and 30 kPa) and CO₂ (0, 10 and 40 kPa) on the RR of ‘Wonderful’ pomegranate arils. These studies showed that low O₂ atmosphere significantly reduced the RR. In addition, 2–4 kPa O₂ was recommended for maintaining qualities of ‘Mollar de Elche’ pomegranate arils by López-Rubira, Conesa, Allende, and Artés (2005). Overall, the results reported in these studies demonstrated that the application of MA systems was effective in maintaining quality and extended shelf life of pomegranate arils. However, low O₂ concentration can cause the build-up of anaerobic atmospheres which then leads to fermentation. Recent studies have introduced the benefits of super-atmospheric O₂ (>70 kPa) to overcome the limitation of low O₂ atmosphere on postharvest physiology and quality maintenance of fresh produce (Belay, Caleb, & Opara, 2017; Maghoumi et al., 2013; Molinu et al., 2016).

In addition, predicting respiratory kinetics of different fruits and vegetables has been based on consideration of...
the RR as a function of gas composition using enzyme kinetics model (Belay et al., 2016; Iqbal et al., 2009; Torrieri, Perone, Cavella, & Masi, 2010). For pomegranate fruit, Caleb, Opara, and Witthuhn (2012b) investigated the effect storage temperature (5, 10 and 15°C) and time on RR of pomegranate arils (cv. Acco and Herskowitz) by using Arrhenius-type model. Similarly, Aindongo et al. (2014) studied the effect of temperature (5, 10, 15 and 22°C) on RR of different pomegranate fractions cv. ‘Bhagwa’ by using Arrhenius equation. These studies reported that temperature had significant effect on RR of pomegranate aril and Arrhenius-type model adequately predicted this effect regarding different temperatures and cultivars used.

On the other hand, the effects of gas composition (2, 10, 21 kPa O<sub>2</sub> and 0, 10, 20 kPa CO<sub>2</sub>) on the RR of pomegranate arils (cv. Hicaz) was studied by Ersan et al. (2010) using Michaelis–Menten (MM) model. The study showed that MAs affected the RR of pomegranate arils and this relationship was best expressed using the MM competitive inhibition model. However, their study did not report on the application of super-atmospheric O<sub>2</sub> condition and its effects on the physiological response of pomegranate arils cv. ‘Wonderful’. In addition, pomegranate fruit undergo a long-term shipping from southern hemisphere (producers) to northern hemisphere (market) and vice versa, prior to processing into arils (Belay et al., 2017). There is limited report on the impacts of this long supply chain on the physiology of the fruit. Therefore, the aim of this study was to investigate the effects of low and super-atmospheric O<sub>2</sub> combined with low and high CO<sub>2</sub> concentrations on the RR of pomegranate arils (cv. Wonderful) after long-term storage. The goal of this study is to provide valuable information on the respiratory kinetics of pomegranate arils cv. ‘Wonderful’, which would guide the role players along the value chain to better design and optimize the postharvest handling and packaging of arils.

**Materials and methods**

**Plant materials and sample preparation**

Pomegranate fruits (cv. Wonderful) were obtained at commercially ripened stage with characteristic deep-red skin and aril with mature kernel (Mphahlele, Caleb, Fawole, & Opara, 2016), from Sonlia Packhouse, Wellington, Western Cape (33° 38’ 23” S, 19° 00’ 40” E), South Africa. Fruits were transported in an air-conditioned and ventilated vehicle to the Postharvest Research Laboratory at Stellenbosch University and stored in a cold room (about 5°C and 95% relative humidity (RHi)) for 4 months until the experiment started. The storage was done to simulate pre-shipping storage plus long-term shipping duration from southern hemisphere production region to the northern hemisphere market and vice versa. Damaged fruits were removed and the outer skin of selected healthy fruits was surface disinfected using 70% ethanol solution (Aindongo et al., 2014). Arils were extracted manually by carefully removing the husk. Extracted arils were collected in a tray and mixed together to create a homogenous batch of all the fruits. Arils (350 g) were transferred to 3000 mL airtight glass jars, which were designed to achieve a completely hermetic seal. The glass jars were prepared in triplicate for each gas mixture and stored at 5°C.

C. Measurement was performed using four gas mixtures as shown in Table 1.

**Experimental set-up**

Rate of O<sub>2</sub> consumption (R<sub>O2</sub>) and CO<sub>2</sub> evolution (R<sub>CO2</sub>) of the arils were measured using a closed system as described by Iqbal et al. (2009), Mahajan and Goswami (2001) and Techavuthiporn and Boonyaritthongchai (2016). Airtight jars of size 3000 mL made up of glass fitted with lid were used. Each jar lid had three valves (inlet, outlet and gas sampling ports). A rubber ring was fixed between the bottle and the lid seal from air leakage. A plastic tube was attached to the inlet valve, which was inserted down to the bottom of the jar to ensure uniform flushing of gas mixture. Before sealing, jars were flushed with humidified air and the selected gas composition, until equilibrium archived. Three jars were flushed for each of the four MAs, resulting in 12 jars. The headspace gas (about 100 µL) was sampled at hourly intervals for the duration of 5 h at 5°C through the silicon septum provided in the jar lid. The headspace gas was analysed for O<sub>2</sub> and CO<sub>2</sub> concentrations using O<sub>2</sub>/CO<sub>2</sub> gas analyser (Checkmate 3, PBI Dansensor, Ringstead, Denmark). This measurement cycle was repeated over a period of 12 days, based on experimental design reported by Ayhan and Esturk (2009). The R<sub>O2</sub> and R<sub>CO2</sub> were calculated using Equations (1) and (2):

\[
R_{O2} = \frac{Y_{O2} - Y_{O2i}}{t - t_i} \times \frac{V_f}{W} \times \frac{1}{RT} \tag{1}
\]

\[
R_{CO2} = \frac{Y_{CO2} - Y_{CO2i}}{t - t_i} \times \frac{V_f}{W} \times \frac{1}{RT} \tag{2}
\]

where \(Y_{O2i}\) and \(Y_{O2}\) are, respectively, O<sub>2</sub> concentration (kPa) at the initial time \(t_i\) (hours, h) and at time \(t\) (h) and \(Y_{CO2i}\) and \(Y_{CO2}\) are, respectively, CO<sub>2</sub> concentration (kPa) at the initial time \(t_i\) (h) and at time \(t\) (h). \(R_{O2}\) and \(R_{CO2}\) are RR in mL/kg h, \(T\) is temperature (Kelvin), \(R\) is universal gas constant (0.008314 kJ/K mol), \(W\) is the total weight of the product (kg) and \(V_f\) is the free volume (\(V_f = V - \frac{W}{\rho}\)), where \(V\) is the volume of the jar (m<sup>3</sup>), \(W\) is the weight of the minimally processed arils (kg) and \(\rho\) the apparent density of the arils (0.98 g/cm<sup>3</sup>). The ratio of CO<sub>2</sub> produced to O<sub>2</sub> consumption is further expressed by the respiration quotient as follows:

\[
RQ = \frac{R_{CO2}}{R_{O2}} \tag{3}
\]

**Development of mathematical model of aril RR**

RR was described by enzyme kinetics approach as a function of one limiting enzymatic reaction in which the substrate is O<sub>2</sub> by using a simple MM model as described in Equation (4).
In order to account for the possible inhibitory effect of CO$_2$, $R_{O_2}$ was described by an MM-type model for change in gas composition under MA storage (Guillard, Guillaume, & Destercke, 2012; Paul & Clarke, 2002). MM competitive inhibition (Equation (5)), where both the inhibitor (CO$_2$) and the substrate (O$_2$) compete for the same active site; uncompetitive (Equation (6)), where CO$_2$ reacts with the substrate–enzyme complex; and non-competitive (Equation (7)), when CO$_2$ reacts both with the enzyme and within the enzyme–substrate complex, models were fitted to the data obtained experimentally to account for the possible effect of CO$_2$ on O$_2$ consumption rate (Gomes, Beaudry, Almeida, & Malcata, 2010). According to Fonseca, Oliveira, and Brecht (2002), during competitive inhibition, the maximum RR is lower in high CO$_2$ concentration, whereas, for uncompetitive inhibition, the maximum RR is not much influenced by high CO$_2$; on the other hand, for non-competitive, the maximum RR lies between competitive and uncompetitive inhibitions. The models variables were analysed and compared to select the best fit of the experimental data (Equations (5)–(7)):

$$R_{O_2} = \frac{V_{\text{max}} \times Y_{O_2}}{K_m \times (1 + Y_{CO_2}/K_i) + Y_{O_2}}$$

(5)

$$R_{O_2} = \frac{V_{\text{max}} \times Y_{O_2}}{K_m + (1 + Y_{CO_2}/K_i) \times Y_{O_2}}$$

(6)

$$R_{O_2} = \frac{V_{\text{max}} \times Y_{O_2}}{(K_m + Y_{O_2}) \times (1 + Y_{CO_2}/K_i)}$$

(7)

where $V_{\text{max}}$ is the maximal value of RR for O$_2$ consumption $R_{O_2}$ (mL/kg h), $Y_{O_2}$ and $Y_{CO_2}$ are the concentrations of O$_2$ and CO$_2$, respectively, inside the glass jar in kPa, $K_m$ is MM constant for O$_2$ consumption and $K_i$ is inhibition constant for CO$_2$ evolution. Estimation of model MM parameters and constants, based on the experimental data, was performed by non-linear regression based on the Levenberg–Marguadrt method using STATISTICA software (vr. 13 StatSoft Inc., Tulsa, USA). The model estimates obtained at each MA conditions were used to describe the dependency of the model parameters on gas composition. The accuracy of the models’ estimation was given by standard error (SE) value.

**Statistical analysis**

The results were presented as mean and standard deviation of three measurements. The data were analysed using STATISTICA software (vr. 13 StatSoft Inc., Tulsa, USA). Two-way ANOVA was used to investigate the effects of atmosphere modification and storage duration on RR of pomegranate arils. Fishers’ least significant difference test was used to determine significant differences among the means of response variables ($p < 0.05$).

**Results and discussion**

**Change in head space gas composition**

Concentrations of O$_2$ and CO$_2$ changed significantly with respect to the different initial gas concentrations and storage duration as shown in Figure 1. The decrease in O$_2$ concentration showed similar trend. Initial O$_2$ concentration of 5 kPa decreased to a concentration of 2.04 kPa for low O$_2$ (MA-1) and from 10 kPa for MA-2 atmospheres at day 12. Similarly, O$_2$ concentration decreased from 21 kPa to 14.06 kPa for air storage and from 70.05 kPa of O$_2$ decreased to 37.83 kPa under super-atmospheric O$_2$. Meanwhile, the headspace CO$_2$ concentration increased in all MA storage from the first day of storage and it reached the recommended range of <10–20 kPa CO$_2$ for pomegranate arils except under MA-3 storage treatment where the CO$_2$ concentration was >20 kPa on day 6. Furthermore, CO$_2$ increased from 9.3 kPa to 15.7 kPa for low O$_2$ atmosphere and from 10.15 kPa to 28.56 kPa under super-atmospheric O$_2$ condition at day 12. However, the increase in CO$_2$ was highest (17.08 kPa) for arils stored under MA-4 at day 12 compared with the initial concentration (0.03 kPa).

Increase in O$_2$ consumption and CO$_2$ production corresponding to different initial gas concentrations were

![Figure 1. Effect of initial gas atmosphere on the change in headspace gas concentration of pomegranate arils stored at 5°C for 12 days. MA-1: (5 kPa O$_2$, 10 kPa CO$_2$ and 85 kPa N$_2$); MA-2: (10 kPa O$_2$, 5 kPa CO$_2$ and 85 kPa N$_2$); MA-3: (70 kPa O$_2$, 10 kPa CO$_2$ and 20 kPa N$_2$); and MA-4 (air).](image-url)
observed. This phenomenon was reflected in the gradual linear reduction of slope for \(O_2\) concentration while coefficients of determination \((R^2)\) for fitted linear models ranged from 0.98 to 0.99 for all MA conditions. The linearity of the model could be attributed to the effect of increasing production of \(CO_2\) and decreasing \(O_2\) concentration over time. The linear changes in \(O_2\) concentration in this study were in agreement with the pattern of a linear decline under aerobic conditions whereas non-linearity can be indicative of anaerobic RR or suppression of respiratory activity due to limited \(O_2\) concentration (Guevara, Yahia, Beaudry, & Cedeño, 2006).

The result showed significant \((p < 0.05)\) effects of storage MA condition and duration on headspace \(O_2\) consumption and \(CO_2\) evolution for arils. Similarly, Ayhan and Esturk (2009) reported high \(CO_2\) concentration (35 kPa) for \(O_2\) enriched atmosphere at 18 days of storage. Accumulation of \(CO_2\) concentration within high \(O_2\) atmosphere was reported by Maghoumi et al. (2014). This study further reported that the presence of high \(O_2\) concentration and accumulation of \(CO_2\) resulted in enhancement of the production of reactive \(O_2\) species that could cause some respiratory stress, increase in RR, induced more \(CO_2\) and depletion of antioxidants. Therefore, the increase in RR at MA-3 in the current study could be associated with the reason of highest accumulation of \(CO_2\).

### Influence of initial gas composition on RR

The potential effect of initial gas concentration on RR of pomegranate arils stored at different MAs was analysed. The results indicated that gas concentration had significant \((p < 0.05)\) effect on RR of pomegranate arils during cold storage. However, the interaction of time and MA types did not significantly affect the RR of pomegranate arils for all MA conditions applied. Based on the calculated RR values obtained from \(O_2\) consumption and \(CO_2\) production, it was observed that RR decreased over storage duration across all MA conditions. Comparing the RR of pomegranate arils at different atmospheres; for low \(O_2\) atmospheres, \(RO_2\) decreased from 3.14 mL/kg h to 0.87 mL/kg h at low \(O_2\) atmosphere for MA-1 and \(RO_2\) decreased from 4.11 mL/kg h to 0.94 mL/kg h for MA-2 and from 7.25 mL/kg h to 2.81 at super-atmospheric \(O_2\) atmosphere. Whereas for arils at ambient atmosphere, \(RO_2\) decreased from 5.16 mL/kg h to 1.95 mL/kg h (Figure 2). Generally, the RR appeared to slow down as time progressed for all MA storage conditions. Furthermore, the effect of \(O_2\) concentration on RR of pomegranate arils clearly showed when the RR decreases with the decrease in \(O_2\) concentration. Similarly, \(RO_2\) pomegranate arils increased from 0.875 mL/kg h to 2.81 ± 0.37 mL/kg h by increasing the \(O_2\) concentration from 5 to 70 kPa at day 12. Lowest \(CO_2\) production rate \((R_{CO_2})\) was observed for arils stored under high \(O_2\) concentration (Figures 2 and 3).

**Figure 2.** Effect of gas concentration on the calculated respiration rate (RR) oxygen (a) and carbon dioxide (b) of minimally processed pomegranate arils stored at 5°C for 12 days. Error bar represents standard deviation of mean values \((n = 3)\) at 95% confident interval. MA-1: (5 kPa \(O_2\), 10 kPa \(CO_2\) and 85 kPa \(N_2\)); MA-2: (10 kPa \(O_2\), 5 kPa \(CO_2\) and 85 kPa \(N_2\)); MA-3: (70 kPa \(O_2\), 10 kPa \(CO_2\) and 20 kPa \(N_2\)); and MA-4 (air).

**Figura 2.** Efecto de la concentración de gas en la frecuencia de respiración (FR) calculada, oxígeno (A) y dióxido de carbono (B) de arilos de granada mínimamente procesados y almacenados a 5°C durante 12 días. La barra de error representa la desviación estándar de los valores medios \((n = 3)\) con un intervalo de confianza de 95%. MA-1: (5 kPa \(O_2\), 10 kPa \(CO_2\) y 85 kPa \(N_2\)); MA-2: (10 kPa \(O_2\), 5 kPa \(CO_2\) y 85 kPa \(N_2\)); MA-3: (70 kPa \(O_2\), 10 kPa \(CO_2\) y 20 kPa \(N_2\)), y MA-4 (aire).
was 1.15 mL/kg h under MA-1 atmosphere compared to MA-2, MA-3 and MA-4. For the other MA conditions (MA-2 and MA-4), which had 10 and 21 kPa initial O₂ concentration, respectively, \( R_{O_2} \) of arils ranging from 0.94 mL/kg h for MA-2 and 1.95 mL/kg h for MA-4 was observed at the end of storage time (day 12).

In addition, reducing the O₂ concentration from 70 to 5 kPa decreased the \( R_{O_2} \) at the same magnitude as \( R_{O_2} \). This finding is supported by the fact that RR decreases with decreasing availability of O₂ through the reduction of overall metabolic activity (Oms-Oliu, Soliva-Fortuny, & Martín-Belloso, 2008). The reduction in RR response due to low O₂ could be a result of decrease in activity of oxidative enzymes such polyphenoloxidase, ascorbic acid oxidase and glycolic acid oxidase (Conesa, Verlinden, Artés-Hernández, Nicolai, & Artés, 2007). MA-2 enhanced CO₂ production rate after 5 days of storage in comparison to MA-1 and MA-4 atmospheres. Furthermore, the rapid depletion of O₂ and accumulation of CO₂ can be related to the low barrier properties of the glass jars used for the experiment. Similarly, low RR of pomegranate arils (cv. Bhicaz) stored at 4°C under a combination of low O₂ (2 kPa) and high CO₂ (10 kPa) was reported by Ersan et al. (2010). The authors reported that the minimum \( R_{O_2} \) of 1.5 mL/kg h and \( R_{CO_2} \) of 0.52 mL/kg h of pomegranate arils was obtained at low O₂ (2 kPa). Aindongo et al. (2014) reported \( R_{O_2} \) and \( R_{CO_2} \) of ‘Bhagwa’ pomegranate arils with ranges 1.9–18.6 mL/kg h and 3.2–28.9 mL/kg h, respectively, stored at 5–22°C, while Caleb, Mahajan, Opara, and Wittuhn (2012) observed \( R_{O_2} \) of 2.5–7.6 mL/kg h and \( R_{CO_2} \) of ranges from 2.7 to 9.0 mL/kg h for pomegranate arils ( cvs. Acco and Herskawitz) stored at 5–15°C. In addition, Banda and others (2015) investigated the effects of different combination of atmospheres (5 kPa O₂ + 10 kPa CO₂ + 85 kPa N₂; 30 kPa O₂ + 10 kPa CO₂ + 60 kPa N₂; 100 kPa N₂; and air) on post-storage RR of ‘Wonderful’ pomegranate arils. The authors reported that \( R_{CO_2} \) significantly changed over time and the highest RR was observed for pomegranate arils stored under passive MA in high barrier films, while arils packed under 100 kPa N₂ maintained the lowest RR (0.58 ± 0.12 kg⁻¹ h⁻¹) at day 12.

Increase in RR (from 1.77 to 2.30 mL/kg h) of pomegranate arils (cv. Malese-Saveh) under 90 kPa O₂ condition has been reported (Maghoumi et al., 2013). Furthermore, increase in RR under super-atmospheric O₂ concentration was reported by Jacksens, Devlieghere, and Debevere (2002) for mushroom, grated celeriac and shredded chicory endives. Similar observation was reported by Allende, Luo, Mc-Evoy, Artés, and Wang (2004) for baby spinach leaves under super-atmospheric O₂ (>70 kPa). The authors observed highest \( R_{O_2} \) and \( R_{CO_2} \) under super-atmospheric O₂ MA condition. The increase in RR was associated with the production of reactive O₂ species and respiratory stress due to the presence of high O₂ concentration (Jacksens et al., 2002). However, the effect of super-atmospheric O₂ depends on the commodity, maturity and ripeness stage, O₂ and CO₂ concentration, time and storage temperature (Kader & Ben-Yehoshua, 2000). Overall, the data suggested that low O₂ atmosphere would be important to lower the RR of pomegranate arils at 5°C compared to super-atmospheric O₂ and passive atmosphere.

**Respiration quotient (RQ)**

The average ratio of CO₂ produced and O₂ consumed (RQ) value of pomegranate arils stored at all MA conditions was within the range of acceptable limit (0.7–1.3) for aerobic respiration of fruits and vegetables (Kader, Zagory, Kerbel, & Wang, 1989). In contrast, arils under super-atmospheric O₂ (MA-3) condition after 10 days of storage had the highest RQ of 1.54. The lowest RQ was observed for pomegranate arils stored under MA-4 treatment. The results further showed that the RQ for all MA conditions increased slightly at the end of 7 d storage.

Based on the assumption that the value of RQ for fresh produce is equal to 1 when the metabolic substrates oxidized during respiration are carbohydrates (Casta-Giraldez, Fito, Ortolà, & Balaguer, 2013; Fonseca et al., 2002), it can be suggested that the fermentation threshold for stored pomegranate arils was not reached across all MA conditions. On the other hand, a slight increase in RQ > 1 suggests that the oxidized substrates were organic acid (Fonseca et al., 2002). Furthermore, Conesa et al. (2007) associated the higher value of RQ with the production of high CO₂ for fresh-cut bell peppers. Similar to the current study, RQ values ranges from 1.14 to 1.26 for minimally processed pomegranate arils ‘Acco’ and ‘Herskawitz’ were reported by Caleb et al. (2012b) and RQ values of 0.9–1.24 for citric acid treated and untreated pomegranate arils (cv. Wonderful) by Banda, Caleb, and Opara (2014) at passive atmosphere.

The results showed that gas concentration had no influence on the RQ of pomegranate arils (as shown in Table 2), except a slight increase (38%) from 0.95 to 1.33 when the O₂ concentration dropped below 2.81 kPa for MA-1 at day 12. Since the lower O₂ limit can be determined by the immediate increase in RQ (Beaudry, 1999), and if the lowest O₂ limit is considered to be the O₂ concentration that causes a 50% increase in the RQ as stated by Hong and Kim (2001), then the lowest O₂ limit of ‘Wonderful’ pomegranate arils can be estimated to be less than 2.8 kPa. This further showed the influence of gas concentration on RQ and the slight but non-significant change in the respiratory process.

**Modelling the influence of gas composition on RR**

MM model with different types of inhibition were tested using the experimental data. The predictions from the MM models as well as the inhibition models (competitive, un-

was observed in MA-3 and low-%

on the metabolic rate atmosphere. This concentration in the %

which’ could be associated with the different concentration (2 kPa), except for competi-

content (2 kPa), except for competitive and non-competitive inhibition model. This could be due to the presence of very low O₂, which can influence effectiveness of MM model, since the model is effective when the reaction is in MM type (Hertog, Peppelenbos, Evelo, & Tijskens, 1998).

Both the maximum O₂ consumption rate and the MM model constant (Vmax,O₂ and KM,O₂) and the CO₂ inhibition constant (KCO₂) were estimated individually from the experimental data obtained at each gas concentration and their MA dependence subsequently studied using Equations (5), (6) and (7). All the four types of MM enzyme kinetics models were capable of describing the O₂ consumption rate as function of MA (MA-2, MA-3 and MA-4 treatments) with observed percentage variance (R² adj = 81–91%). Whereas, lower percentage variance of R² adj > 70% were found for (MA-1) which had the lowest initial O₂ concentration (2 kPa), except for competitive inhibition model. This could be due to the presence of very low O₂, which can influence effectiveness of MM model, since the model is effective when the reaction is in MM type (Hertog, Peppelenbos, Evelo, & Tijskens, 1998).

The authors found relatively higher KCO₂ values, which showed the extent to which RR can be inhibited by CO₂ in Table 3, the simultaneous existence of competitive, un-competitive and non-competitive inhibition were observed depending on the initial gas concentration. Comparing all models, relatively higher KCO₂ value was observed in MA-1 during competitive inhibition model, which implies inhibition by CO₂ has not occurred, whereas, a slight un-competitive and non-competitive inhibition was observed. This indicated that a model which combined un-competitive and non-competitive inhibition could better explain the CO₂ effect on the RR (Guillard et al., 2012). On the contrary, the RR of pomegranate arils for the other atmospheres was competitive inhibition, with the lowest KCO₂. However, the influence of CO₂ on the metabolic rate could be due to its effect on changing the pH than its direct influence on enzymatic reaction (Torrieri et al., 2010).

Comparing simple and inhibition models for each atmo-
sphere, there was no clear difference on effect of CO₂ on O₂ consumption rate for all MAs. However, according to the KCO₂ values, which showed the extent to which RR can be inhibited by CO₂ in Table 3, the simultaneous existence of competitive, un-competitive and non-competitive inhibition were observed depending on the initial gas concentration. Comparing all models, relatively higher KCO₂ value was observed in MA-1 during competitive inhibition model, which implies inhibition by CO₂ has not occurred, whereas, a slight un-competitive and non-competitive inhibition was observed. This indicated that a model which combined un-competitive and non-competitive inhibition could better explain the CO₂ effect on the RR (Guillard et al., 2012). On the contrary, the RR of pomegranate arils for other atmospheres was competitive inhibition, with the lowest KCO₂. However, the influence of CO₂ on the metabolic rate could be due to its effect on changing the pH than its direct influence on enzymatic reaction (Torrieri et al., 2010).

The Vmax,O₂ values obtained from the current experiment were similar to those reported by Ersan et al. (2010) for ‘Hicaz’ pomegranate arils at 5°C. At low O₂, Vmax,O₂ of 3.6 mL kg⁻¹h⁻¹ was comparable to 3.1 mL kg⁻¹h⁻¹ reported by Ersan et al. (2010). In contrast, the KCO₂ and KM,O₂ values were different. The authors found relatively higher KM,O₂ ranging from 3.8 to 5.1 for ‘Hicaz’ pomegranate arils, whereas the values in the current experiment were within the range of 0.29–2.67 for ‘Wonderful’ under low-O₂ atmosphere. This variation in KM,O₂ could be associated with the different model-fitting methods used. Ersan et al. (2010) linearized the data before fitting, while for the current study a non-linear regression model has been used, since linearization is equivalent to changing the weight given to the data in the estimation procedure and it should be avoided (Fonseca et al., 2002).

Comparing the accuracy of the parameter estimates by using the estimated SEs for all models, small SE values of all Vmax,O₂ and KM,O₂ were observed. Low SE values (lower
value than the sample mean) for the parameter estimates can be considered as well defined (Hertog, Lammertyn, Scheerlinck, & Nicolaï, 2007). Thus, it can be concluded that the models accurately predicted the influence of MA on the RR of ‘Wonderful’ pomegranate arils. On the other hand, the accuracy for the competitive and non-competitive inhibition model for MA-1 and for non-competitive inhibition for MA-3 could be less defined by the increase

Figure 3. Correlation of head space \(O_2\) concentration (kPa) on the \(O_2\) consumption rate (mL/kg h) of minimally processed pomegranate arils stored at 5°C for 12 days in a closed system. MA-1: (5 kPa \(O_2\), 10 kPa \(CO_2\) and 85 kPa \(N_2\)); MA-2: (10 kPa \(O_2\), 5 kPa \(CO_2\) and 85 kPa \(N_2\)); MA-3: (70 kPa \(O_2\), 10 kPa \(CO_2\) and 20 kPa \(N_2\)); and MA-4 (air).

in SE for $K_m$. However, the higher SE could also explain the coexistence of both competitive and uncompetitive inhibition of RR by CO$_2$ (Hertog et al., 2007). Furthermore, the model parameters were statistically significant ($p < 0.05$) and the correlation coefficient of determination was $R^2 = 0.85$–0.97% for all atmospheres. This showed a good fit of the model to the experimental data. Therefore, these results demonstrated that the MM enzyme kinetics models can be used to describe the dependency of RR of pomegranate arils on the modified storage atmospheres. Since the results for MA-2, MA-3 and MA-4 showed a competitive inhibition RR and a slight combination of competitive and un-competitive inhibition for MA-1, a non-linear regression was applied to the whole set of experimental data using competitive model. The model adequately predicted the O$_2$ consumption rate ($R^2 = 0.94\%$) as shown in Figure 4, with a normal distribution of the residual values. Based on this result, it can be suggested that competitive inhibition can be able to describe the effect of CO$_2$ to O$_2$ consumption rate at low and super-atmospheric O$_2$ condition.

**Conclusion**

This study showed that RR of pomegranate arils (cv. Wonderful) was significantly affected by initial gas concentrations during storage. Low O$_2$ MA conditions reduced the RR of the arils. In contrast, the use of super-atmospheric O$_2$ concentration (70 kPa) induced physiological stress, and consequently slightly increased the RR of arils. Based on the respiratory kinetics of pomegranate arils, this study showed that super-atmospheric O$_2$ is of limited or no benefit in slowing down the metabolic process of pomegranate arils. The MM enzyme kinetics model (using competitive-inhibition-type equation) adequately described the effect of CO$_2$ on O$_2$ consumption rate at low O$_2$ (5 kPa), super-atmospheric O$_2$ (70 kPa) and enriched CO$_2$ concentrations. The parameter estimates obtained provide a guiding step for the management of MA systems to avoid unfavourable conditions for pomegranate arils (cv. Wonderful).
